### **Definition**

#### Monolithic

A monolithic application is self-contained, and independent from other computing applications. The design philosophy is that the application is responsible not just for a particular task, but can perform every step needed to complete a particular function.

#### Microservices

Microservices is a software development technique that arranges an application as a collection of loosely coupled services.

https://en.wikipedia.org/wiki/Monolithic\_application https://en.wikipedia.org/wiki/Microservices

- Unit design
  - The application consists of loosely coupled services.
  - Each service supports a single business task.

- Unit design
  - The application consists of loosely coupled services.
  - Each service supports a single business task.
- Plexibility
  - Each microservice can be developed using a programming language and framework that best suits.

- Unit design
  - The application consists of loosely coupled services.
  - Each service supports a single business task.
- Flexibility
  - Each microservice can be developed using a programming language and framework that best suits.
- Maintainability
  - Simple, focused, and independent. So the application is easier to maintain.

- Unit design
  - The application consists of loosely coupled services.
  - Each service supports a single business task.
- Plexibility
  - Each microservice can be developed using a programming language and framework that best suits.
- Maintainability
  - Simple, focused, and independent. So the application is easier to maintain.
- Resiliency
  - The application functionality is distributed across multiple services.
  - If a microservice fails, the functionality offered by the others continues to be available.

- Unit design
  - The application consists of loosely coupled services.
  - Each service supports a single business task.
- Flexibility
  - Each microservice can be developed using a programming language and framework that best suits.
- Maintainability
  - Simple, focused, and independent. So the application is easier to maintain.
- Resiliency
  - The application functionality is distributed across multiple services.
  - If a microservice fails, the functionality offered by the others continues to be available.
- Scalability
  - Each microservice can be scaled independently of the other services.

- Function Boundary

https://martinfowler.com/bliki/BoundedContext.html

# Communication Design

#### HTTP communication

Also known as **Synchronous communication**, the calls between services is a viable option for **service-to-service** via REST API.

#### Message communication

Also known as **Asynchronous communication**, the services push messages to a message broker that other services subscribe to.

#### Event-driven communication

Another type of **Asynchronous communication**, the services does not need to know the common message structure. Communication between services takes place via events that individual services produce.

https://blog.logrocket.com/methods-for-microservice-communication

### HTTP communication

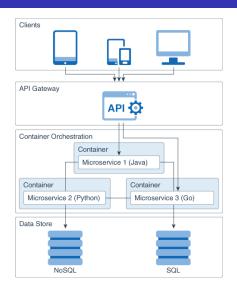

Figure: Synchronous calls

### Event-driven communication

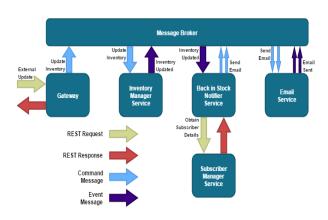

Figure: Asynchronous calls

https://capgemini.github.io/architecture/is-rest-best-microservices

# Why not SOAP?

It is possible to build a microservices-based architecture using SOAP which uses HTTP. But:

- it only uses POST messages to transfer data to a server.
- SOAP lacks concepts such as HATEOAS that enable relationships between microservices to be handled flexibly.
- The interfaces have to be completely defined by the server and known on the client.

Microservices; Flexible Software Architecture. "Eberhard Wolff"

## **API** Gateway

### **API** Gateway

API Gateway is a tool that makes it easy for developers to create(1), publish(2), maintain(3), monitor(4), and secure(5) APIs at any scale. APIs act as the "front door" for applications to access data, business logic, or functionality from your backend services.

## Service Discovery

#### **Problem**

In any distributed architecture, we need to find the physical address of where a machine is located.

#### Solution

Using service discovery, a service can register itself when it is up and healthy. By using such technology you can achieve:

- Load balanced
  - dynamically load balance requests across all service instances to ensure that the service invocations are spread across all the service instances managed by it.

## Service Discovery

#### **Problem**

In any distributed architecture, we need to find the physical address of where a machine is located.

#### Solution

Using service discovery, a service can register itself when it is up and healthy. By using such technology you can achieve:

- Load balanced
  - dynamically load balance requests across all service instances to ensure that the service invocations are spread across all the service instances managed by it.
- 2 Resilient
  - client should "cache" service information locally. Local caching allows for gradual degradation of the service discovery feature so that if service discovery service does become unavailable, applications can still function and locate the services based on the information maintained in its local cache.

## Service Discovery

#### **Problem**

In any distributed architecture, we need to find the physical address of where a machine is located.

#### Solution

Using service discovery, a service can register itself when it is up and healthy. By using such technology you can achieve:

- Load balanced
  - dynamically load balance requests across all service instances to ensure that the service invocations are spread across all the service instances managed by it.
- Resilient
  - client should "cache" service information locally. Local caching allows for gradual degradation of the service discovery feature so that if service discovery service does become unavailable, applications can still function and locate the services based on the information maintained in its local cache.
- Fault-tolerant
  - detect when a service instance isn't healthy and remove the instance from the list of available services.

The Twelve-Factor App methodology is a methodology for building software-as-a-service applications

- Codebase
- ② Dependencies
- Config
- Backing services
- Build, release, run
- Opening Processes

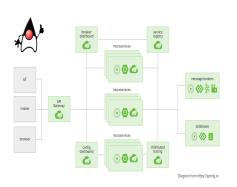

- Port binding
- Concurrency
- Oisposability
- Dev/prod parity
- Logs
- Admin processes

https://12factor.net

- Codebase
  - One codebase tracked in revision control, many deploys

- ② Dependencies
  - Explicitly declare and isolate dependencies
  - Consider the magic key Portability

```
<dependencies>
    <dependency>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter-data-jpa</artifactId>
    </dependency>
    <dependency>
        <groupId>mysql</groupId>
        <artifactId>mysql-connector-java</artifactId>
    </dependency>
    <dependency>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter-tomcat</artifactId>
        <scope>compile</scope>
    </dependency>
    <dependency>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter-web</artifactId>
    </dependency>
    <dependency>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter-actuator</artifactId>
        <version>2.3.0.RELEASE
    </dependency>
    <dependency>
        <groupId>org.springframework.cloud</groupId>
        <artifactId>spring-cloud-starter-config</artifactId>
    </dependency>
    <dependency>
        <groupId>org.springframework.cloud</groupId>
        <artifactId>spring-cloud-starter-zipkin</artifactId>
    </dependency>
    <dependency...>
    <dependency...>
    <dependency...>
    <dependency...>
</dependencies>
```

- Configuration
  - Config is what is changed from environment to another

- Configuration
  - Config is what is changed from environment to another
  - Config should be provided by the environment, not the code

- Configuration
  - Config is what is changed from environment to another
  - Config should be provided by the environment, not the code
  - Credentials are not configuration, but secrets
    - Never ever store credentials in code
    - Don't save credentials in PLAINTEXT with config, but hashed

- Configuration
  - Config is what is changed from environment to another
  - Config should be provided by the environment, not the code
  - Credentials are not configuration, but secrets
    - Never ever store credentials in code
    - Don't save credentials in PLAINTEXT with config, but hashed
  - Configuration in Legacy system is a challenge
    - Unlike missing dependencies, System will not immediately crashed if configuration is missed
    - Give attention to URLs in legacy code

## Externalized and Dynamic Configurations

#### **Problem**

Configurations will vary from environment to another, How to manage them?

#### Solution

Centralize your configuration

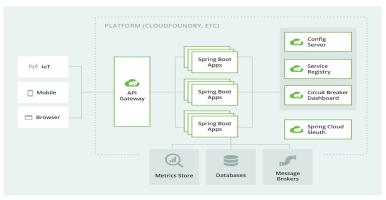

Figure: Microservices with Spring Cloud

# **Available Market Options**

Figure: Popular Config Stores

### Circuit Breaker Pattern

#### **Problem**

• One of the big differences between in-memory calls and remote calls is that remote calls can fail, or hang without a response until some timeout limit is reached.

#### Solution

#### Fault Tolerance

Figure: Circuit Breaker

### Circuit Breaker Pattern

#### **Problem**

- One of the big differences between in-memory calls and remote calls is that remote calls can fail, or hang without a response until some timeout limit is reached.
- What's worse if you have many callers on a unresponsive supplier, then you can run out of critical resources leading to cascading failures across multiple systems.

#### Solution

#### Fault Tolerance

Figure: Circuit Breaker

- Backing Service
  - A backing service is any service the app consumes over the network as part of its normal operation.
  - Examples include data stores, queueing, and caching systems

### Backing Service

- A backing service is any service the app consumes over the network as part of its normal operation.
- Examples include data stores, queueing, and caching systems

#### How to achieve that?

• To the App, this is just normal service.

### Backing Service

- A backing service is any service the app consumes over the network as part of its normal operation.
- Examples include data stores, queueing, and caching systems

#### How to achieve that?

- To the App, this is just normal service.
- Should be treating as attached resource.

### Backing Service

- A backing service is any service the app consumes over the network as part of its normal operation.
- Examples include data stores, queueing, and caching systems

#### How to achieve that?

- To the App, this is just normal service.
- Should be treating as attached resource.
- Even with third party services like SMTP providers, it is just a resource.

### Backing Service

- A backing service is any service the app consumes over the network as part of its normal operation.
- Examples include data stores, queueing, and caching systems

#### How to achieve that?

- To the App, this is just normal service.
- Should be treating as attached resource.
- Even with third party services like SMTP providers, it is just a resource.
- A good way for this is as mentioned in config talk.

```
public void useHardCodedResources(long userId) {
    final String URL = "https://10.20.30.90/api/user/";

User user = restTemplate.getObject(URL + userId, User.class);

...

public void useAttachedResources(String resourceConfig, long userId) {
    User user = restTemplate.getObject(resourceConfig + userId, User.class);
    ...
}
```

### Backing Service

- A backing service is any service the app consumes over the network as part of its normal operation.
- Examples include data stores, queueing, and caching systems

#### How to achieve that?

- To the App, this is just normal service.
- Should be treating as attached resource.
- Even with third party services like SMTP providers, it is just a resource.
- A good way for this is as mentioned in config talk.

```
public void useHardCodedResources(long userId) {
    final String URL = "https://10.20.30.90/api/user/";
    User user = restTemplate.getObject(URL + userId , User.class);
    ...
}

public void useAttachedResources(String resourceConfig, long userId) {
    User user = restTemplate.getObject(resourceConfig + userId , User.class);
    ...
}
```

• This way you can switch between services smoothly on different environments via configurations provided by the environment.

Figure: CI Workflow

- Suild, Release and Run (CI & CD)
  - Release
    - The process where you combine the build with deploy's config.

- Build, Release and Run (CI & CD)
  - Release
    - The process where you combine the build with deploy's config.
    - If the tests passed , build stage is done; and move to release stage.

- Build, Release and Run (CI & CD)
  - Release
    - The process where you combine the build with deploy's config.
    - If the tests passed , build stage is done; and move to release stage.
    - The resulting release contains both the build and the config and is ready for immediate execution in the execution environment.

- Build, Release and Run (CI & CD)
  - Release
    - The process where you combine the build with deploy's config.
    - If the tests passed , build stage is done; and move to release stage.
    - The resulting release contains both the build and the config and is ready for immediate execution in the execution environment.
    - Every release should always have a unique release ID, such as a timestamp of the release (such as 2011-04-06-20:32:17) or an incrementing number (such as v100).

- Build, Release and Run (CI & CD)
  - Release
    - The process where you combine the build with deploy's config.
    - If the tests passed , build stage is done; and move to release stage.
    - The resulting release contains both the build and the config and is ready for immediate execution in the execution environment.
    - Every release should always have a unique release ID, such as a timestamp of the release (such as 2011-04-06-20:32:17) or an incrementing number (such as v100).
    - Release are immutable, any change should be mapped with a new release.

### 3 Build, Release and Run (CI & CD)

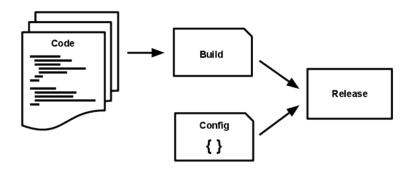

- Release
  - The process where you combine the build with deploy's config.
  - If the tests passed , build stage is done; and move to release stage.
  - The resulting release contains both the build and the config and is ready for immediate execution in the execution environment.
  - Every release should always have a unique release ID, such as a timestamp of the release (such as 2011-04-06-20:32:17) or an incrementing number (such as v100).
  - Release are immutable, any change should be mapped with a new release.
  - Using tagging, unique IDs and timestamp will be the only way to apply rollback if you want.

- Build, Release and Run (CI & CD)
  - Run
    - also known as "runtime", runs the app in the execution environment, by launching some set of the app's processes against a selected release.

- Build, Release and Run (CI & CD)
  - Run
    - also known as "runtime", runs the app in the execution environment, by launching some set of the app's processes against a selected release.
    - Builds are initiated by the app's developers whenever new code is deployed.
       Runtime execution, by contrast, can happen automatically in cases such as a server reboot, or a crashed process being restarted by the process manager.

- Build, Release and Run (CI & CD)
  - Run
    - also known as "runtime", runs the app in the execution environment, by launching some set of the app's processes against a selected release.
    - Builds are initiated by the app's developers whenever new code is deployed.
       Runtime execution, by contrast, can happen automatically in cases such as a server reboot, or a crashed process being restarted by the process manager.
    - the run stage should be kept to as few moving parts as possible, since problems that prevent an app from running can cause it to break in the middle of the night when no developers are on hand.

• Build, Release and Run (CI & CD) Strictly separate build and run stages. In Microservices, this process is always related directly to development culture; How to be sure each time work will be delivered correctly?

Opening Processes

Execute the app as one or more **stateless** processes

 Twelve-factor processes are stateless and share-nothing, and indeed Microservices are the same.

#### Opening Processes

Execute the app as one or more stateless processes

- Twelve-factor processes are stateless and share-nothing, and indeed Microservices are the same.
- Any data that needs to persist must be stored in a stateful backing service, typically a database.

#### Opening Processes

Execute the app as one or more **stateless** processes

- Twelve-factor processes are stateless and share-nothing, and indeed Microservices are the same.
- Any data that needs to persist must be stored in a stateful backing service, typically a database.
- Asset packagers like django-assetpackager use the filesystem as a cache for compiled assets. This process of compiling should be done during the build stage.

#### Opening Processes

Execute the app as one or more **stateless** processes

- Twelve-factor processes are stateless and share-nothing, and indeed Microservices are the same.
- Any data that needs to persist must be stored in a stateful backing service, typically a database.
- Asset packagers like django-assetpackager use the filesystem as a cache for compiled assets. This process of compiling should be done during the build stage.
- For example, using filesystems and caching memory is a violation of twelve factor.

#### Opening Processes

Execute the app as one or more **stateless** processes

- Twelve-factor processes are stateless and share-nothing, and indeed Microservices are the same.
- Any data that needs to persist must be stored in a stateful backing service, typically a database.
- Asset packagers like django-assetpackager use the filesystem as a cache for compiled assets. This process of compiling should be done during the build stage.
- For example, using filesystems and caching memory is a violation of twelve factor.
- Session state data is a good candidate for a datastore that offers time-expiration, such as Memcached or Redis.

#### Opening Processes

Execute the app as one or more **stateless** processes

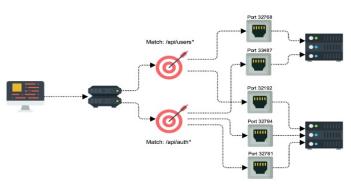

- Twelve-factor processes are stateless and share-nothing, and indeed Microservices are the same.
- Any data that needs to persist must be stored in a stateful backing service, typically a database.
- Asset packagers like django-assetpackager use the filesystem as a cache for compiled assets. This process of compiling should be done during the build stage.
- For example, using filesystems and caching memory is a violation of twelve factor.
- Session state data is a good candidate for a datastore that offers time-expiration, such as Memcached or Redis.
- It is important to know also that, Microservices must be totally stateless, and there
  is no way to keep state for backend services http requests.

Port Binding
 Export services via port binding

#### Port Binding

Export services via port binding

 The Microservice is self-contained and does not rely on injection of a webserver to create a web-facing service.

#### Port Binding

Export services via port binding

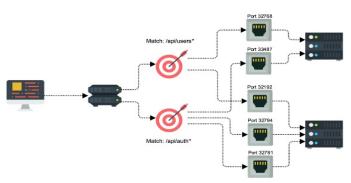

- The Microservice is self-contained and does not rely on injection of a webserver to create a web-facing service.
- In a local development environment, you can visit a service URL like http://localhost:5000/ to access the service exported by their app.

### Port Binding

Export services via port binding

- The Microservice is self-contained and does not rely on injection of a webserver to create a web-facing service.
- In a local development environment, you can visit a service URL like http://localhost:5000/ to access the service exported by their app.
- In deployment, a routing layer handles routing requests from a public-facing hostname to the port-bound web processes.

In old monilithic style, life was someway easy, but with microservices data management; you need to play harder.

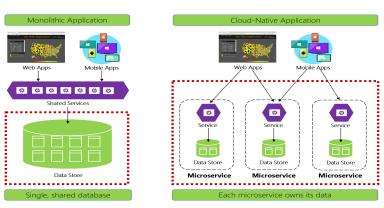

Figure: Distributed Data Architecture

### Why database per service?

• Domain data is encapsulated within the service

#### Why database per service?

- Domain data is encapsulated within the service
- Data schema can evolve without directly impacting other services code and functionality

#### Why database per service?

- Domain data is encapsulated within the service
- Data schema can evolve without directly impacting other services code and functionality
- Each data store can independently scale

#### Why database per service?

- Domain data is encapsulated within the service
- Data schema can evolve without directly impacting other services code and functionality
- Each data store can independently scale
- Data store failure in one service won't directly impact other services

#### Why database per service?

- Domain data is encapsulated within the service
- Data schema can evolve without directly impacting other services code and functionality
- Each data store can independently scale
- Data store failure in one service won't directly impact other services

#### **BUT**

You can also use single DB server and achieve some sort of that, How?

#### Why database per service?

- Domain data is encapsulated within the service
- Data schema can evolve without directly impacting other services code and functionality
- Each data store can independently scale
- Data store failure in one service won't directly impact other services

#### **BUT**

You can also use single DB server and achieve some sort of that, How?

Schema management; that is each service has its own schema

#### Why database per service?

- Domain data is encapsulated within the service
- Data schema can evolve without directly impacting other services code and functionality
- Each data store can independently scale
- Data store failure in one service won't directly impact other services

#### **BUT**

You can also use single DB server and achieve some sort of that, How?

- Schema management; that is each service has its own schema
- Tables' access privilege

#### Why database per service?

- Data schema can evolve without directly impacting other services code and functionality
- Each data store can independently scale
- Data store failure in one service won't directly impact other services

#### BUT

You can also use single DB server and achieve some sort of that, How?

- Schema management; that is each service has its own schema
- Tables' access privilege
- Database readonly views

#### Why database per service?

- Domain data is encapsulated within the service
- Data schema can evolve without directly impacting other services code and functionality
- Each data store can independently scale
- Data store failure in one service won't directly impact other services

#### BUT

You can also use single DB server and achieve some sort of that, How?

- Schema management; that is each service has its own schema
- Tables' access privilege
- Database readonly views

#### Which way is better?

A: It depends. However it is recommended to follow best practices.

The more simple and focused service you have, the easier management you get. A perfect way to do that, is applying DDD principles.

#### Why database per service?

#### Which way is better?

A: It depends. However it is recommended to follow best practices.

The more simple and focused service you have, the easier management you get. A perfect way to do that, is applying DDD principles.

While encapsulating data into separate microservices can increase agility, performance, and scalability, it also presents many challenges.

#### Cross-Service Queries

Usually you need to integrate to get\query data from other services

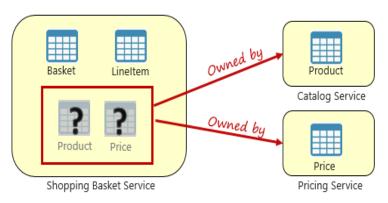

Figure: Querying across microservices

https://docs.microsoft.com/en-us/dotnet/architecture/cloud-native/distributed-data

#### Cross-Service Queries

Usually you need to integrate to get\query data from other services

• First and easiest way is to query service's database directly, Anti-Pattern

#### Cross-Service Queries

Usually you need to integrate to get\query data from other services

- First and easiest way is to query service's database directly, Anti-Pattern
- Also another simple way is through HTTP, but this may leads to coupling issues

#### Cross-Service Queries

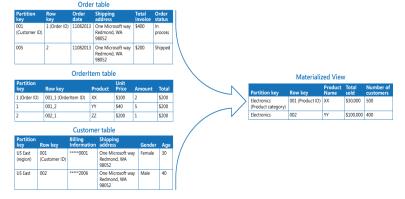

Usually you need to integrate to get\query data from other services

- First and easiest way is to query service's database directly, Anti-Pattern
- Also another simple way is through HTTP, but this may leads to coupling issues
- Third option is using asynchronous calls via queues, and you should give attention to this

#### Cross-Service Queries

Usually you need to integrate to get\query data from other services

- First and easiest way is to query service's database directly, Anti-Pattern
- Also another simple way is through HTTP, but this may leads to coupling issues
- Third option is using asynchronous calls via queues, and you should give attention to this
- If the data volume is huge, and is not changed quickly, good way to use is

#### Distributed Transactions

We move from a world of **immediate consistency** to that of **eventual consistency** That is; in microservices. You can't depend on ACID transaction, but **BASE** which is acronym for **B**asic **A**vailability, **S**oft-state, and **E**ventual consistency

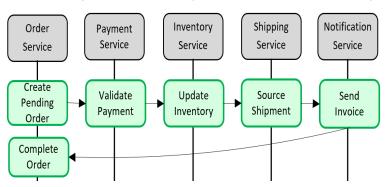

Figure: Transaction across microservices

https://docs.microsoft.com/en-us/dotnet/architecture/cloud-native/distributed-data

#### Distributed Transactions

• Having multiple data sources on different zones will make consistency issue

- Having multiple data sources on different zones will make consistency issue
- No options to handle that except Programmatic approach

- Having multiple data sources on different zones will make consistency issue
- No options to handle that except Programmatic approach
- First available way is 2-Phase-commits 2PC

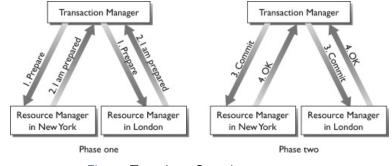

Figure: Two-phase Commit pattern

#### Distributed Transactions

- Having multiple data sources on different zones will make consistency issue
- No options to handle that except Programmatic approach
- First available way is 2-Phase-commits 2PC

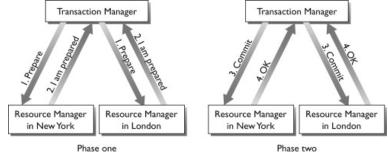

Figure: Two-phase Commit pattern

In real case, this is impractical, and will lead to locking and time consuming issue

- Having multiple data sources on different zones will make consistency issue
- No options to handle that except Programmatic approach
- First available way is 2-Phase-commits 2PC

- Having multiple data sources on different zones will make consistency issue
- No options to handle that except Programmatic approach
- First available way is 2-Phase-commits 2PC
- $\bullet \ \, \text{Another approach; If moving from point to point is succeeded, continue; else } \textbf{Compensate} \\$

- Having multiple data sources on different zones will make consistency issue
- No options to handle that except Programmatic approach
- First available way is 2-Phase-commits 2PC
- Another approach; If moving from point to point is succeeded, continue; else Compensate
- The big father of this approach is Saga pattern

Command and Query Responsibility Segregation (CQRS)

Cloud native applications need sometimes to handle huge data.

#### Command and Query Responsibility Segregation (CQRS)

Cloud native applications need sometimes to handle huge data.

• In monolithic, there is no problem to handle this for simple CRUD operations

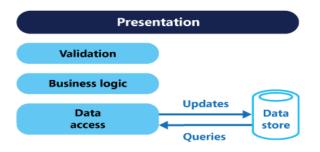

Figure: Traditional Application Architecture

### Command and Query Responsibility Segregation (CQRS)

Cloud native applications need sometimes to handle huge data.

- In monolithic, there is no problem to handle this for simple CRUD operations
- Adding good managed indexes for example can solve the issue

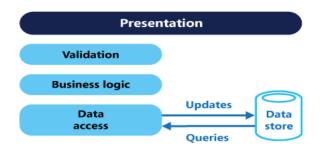

Figure: Traditional Application Architecture

### Command and Query Responsibility Segregation (CQRS)

Cloud native applications need sometimes to handle huge data.

- In monolithic, there is no problem to handle this for simple CRUD operations
- Adding good managed indexes for example can solve the issue
- But read is not only the concern you focus on, but also writes

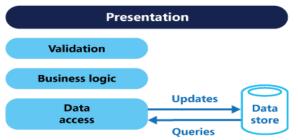

Figure: Traditional Application Architecture

### Command and Query Responsibility Segregation (CQRS)

Cloud native applications need sometimes to handle huge data.

- In monolithic, there is no problem to handle this for simple CRUD operations
- Adding good managed indexes for example can solve the issue
- But read is not the only matter you focus on, but also writes
- Then, we have two concerns; read and write, and this is what CQRS intends to do

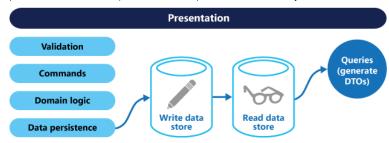

Figure: CQRS Application Architecture

### Command and Query Responsibility Segregation (CQRS)

- In monolithic, there is no problem to handle this for simple CRUD operations
- Adding good managed indexes for example can solve the issue
- But read is not only the concern you focus on, but also writes
- Then, we have two concerns; read and write, and this is what CQRS intends to do

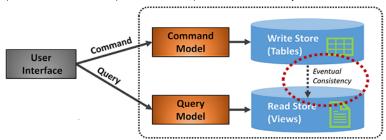

Figure: CQRS Implementation

### Command and Query Responsibility Segregation (CQRS)

- In monolithic, there is no problem to handle this for simple CRUD operations
- Adding good managed indexes for example can solve the issue
- But read is not only the concern you focus on, but also writes
- Then, we have two concerns; read and write, and this is what CQRS intends to do
- You should give attention to Eventual Consistency

### Command and Query Responsibility Segregation (CQRS)

- In monolithic, there is no problem to handle this for simple CRUD operations
- Adding good managed indexes for example can solve the issue
- But read is not only the concern you focus on, but also writes
- Then, we have two concerns; read and write, and this is what CQRS intends to do
- You should give attention to Eventual Consistency
  - I watch the weather report and learn that it's going to rain tomorrow.

### Command and Query Responsibility Segregation (CQRS)

- In monolithic, there is no problem to handle this for simple CRUD operations
- Adding good managed indexes for example can solve the issue
- But read is not only the concern you focus on, but also writes
- Then, we have two concerns; read and write, and this is what CQRS intends to do
- You should give attention to Eventual Consistency
  - I watch the weather report and learn that it's going to rain tomorrow.
  - I tell you that it's going to rain tomorrow.

### Command and Query Responsibility Segregation (CQRS)

- In monolithic, there is no problem to handle this for simple CRUD operations
- Adding good managed indexes for example can solve the issue
- But read is not only the concern you focus on, but also writes
- Then, we have two concerns; read and write, and this is what CQRS intends to do
- You should give attention to Eventual Consistency
  - 1 watch the weather report and learn that it's going to rain tomorrow.
  - ② I tell you that it's going to rain tomorrow.
  - 3 Your neighbor tells his wife that it's going to be sunny tomorrow.

### Command and Query Responsibility Segregation (CQRS)

- In monolithic, there is no problem to handle this for simple CRUD operations
- Adding good managed indexes for example can solve the issue
- But read is not only the concern you focus on, but also writes
- Then, we have two concerns; read and write, and this is what CQRS intends to do
- You should give attention to Eventual Consistency
  - 1 watch the weather report and learn that it's going to rain tomorrow.
  - 2 I tell you that it's going to rain tomorrow.
  - 3 Your neighbor tells his wife that it's going to be sunny tomorrow.
  - 4 You tell your neighbor that it is going to rain tomorrow.

### Command and Query Responsibility Segregation (CQRS)

- In monolithic, there is no problem to handle this for simple CRUD operations
- Adding good managed indexes for example can solve the issue
- But read is not only the concern you focus on, but also writes
- Then, we have two concerns; read and write, and this is what CQRS intends to do
- However you need to make your data always in a sync mode
- You should give attention to Eventual Consistency
- You need also to make your query model always in a sync state

### Command and Query Responsibility Segregation (CQRS)

Cloud native applications need sometimes to handle huge data.

- In monolithic, there is no problem to handle this for simple CRUD operations
- Adding good managed indexes for example can solve the issue
- But read is not only the concern you focus on, but also writes
- Then, we have two concerns; read and write, and this is what CQRS intends to do
- However you need to make your data always in a sync mode
- You should give attention to Eventual Consistency
- You need also to make your query model always in a sync state
- A good way to achieve this, is to use Event Sourcing Pattern

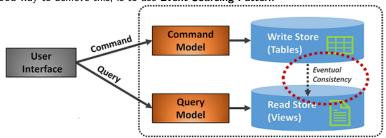

Figure: CQRS Implementation

### **Event Sourcing Pattern**

Applying a list of events in atomic way is very hard to be applied using distributed transactions!

### **Event Sourcing Pattern**

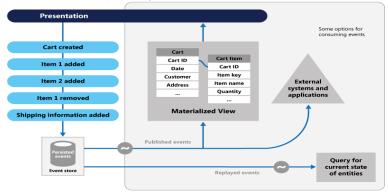

Applying a list of events in atomic way is very hard to be applied using distributed transactions!

• How did we get there? (History is always matter)

#### **Event Sourcing Pattern**

Applying a list of events in atomic way is very hard to be applied using distributed transactions!

- How did we get there? (History is always matter)
- An approach to handling operations on data that's driven by a sequence of events, each of which is recorded in an append-only store

#### **Event Sourcing Pattern**

By applying this pattern, you will have

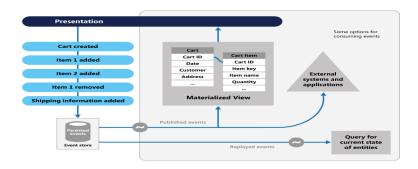

Figure: Event Sourcing

#### **Event Sourcing Pattern**

By applying this pattern, you will have

 Better performance, that is your the application code that generates the events will be decoupled from the actual code

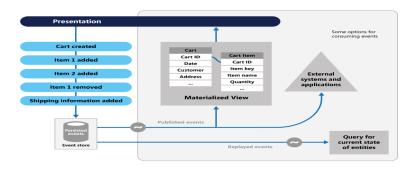

Figure: Event Sourcing

#### **Event Sourcing Pattern**

By applying this pattern, you will have

- Better performance, that is your the application code that generates the events will be decoupled from the actual code
- More power to scale up!

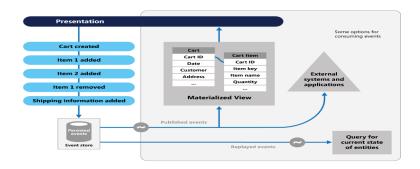

Figure: Event Sourcing

#### **Event Sourcing Pattern**

By applying this pattern, you will have

- Better performance, that is your the application code that generates the events will be decoupled from the actual code
- More power to scale up!
- Log history which is fundamental need in any project

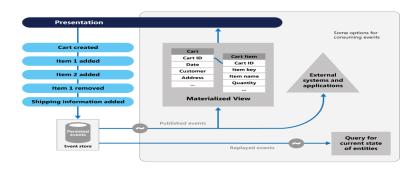

Figure: Event Sourcing

#### **Event Sourcing Pattern**

By applying this pattern, you will have

- Better performance, that is your the application code that generates the events will be decoupled from the actual code
- More power to scale up!
- Log history which is fundamental need in any project
- prevent concurrent updates from causing conflicts because it avoids the requirement to directly update objects in the data store

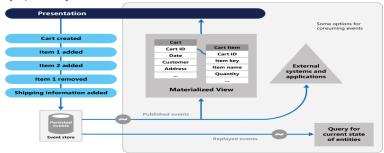

Figure: Event Sourcing

### Caching Pattern

#### Caching Pattern

Calling backing services is a heavy process, and to overcome this issue; you need to have some shared data store to be fully managed in run-time across all instances.

• How can multiple instances within multiple apps share something?

#### Caching Pattern

- How can multiple instances within multiple apps share something?
- Why not just loading on startup? In-memory caching

#### Caching Pattern

- How can multiple instances within multiple apps share something?
- Why not just loading on startup? In-memory caching
- Caching service is the solution. Distributed caching

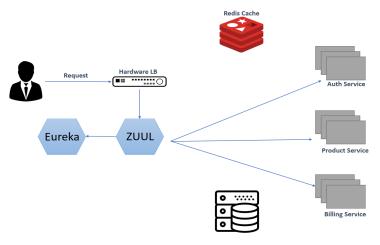

Figure: Typical Scenario

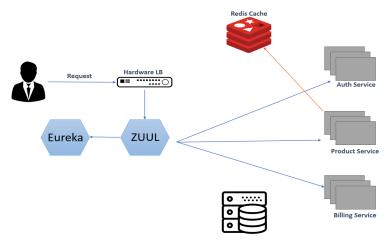

Figure: Typical Scenario

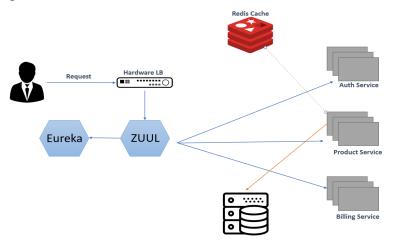

Figure: Typical Scenario

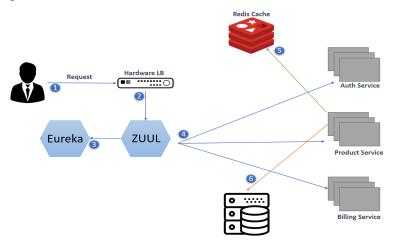

Figure: Typical Scenario

#### Caching Pattern

- How can multiple instances within multiple apps share something?
- Why not just loading on startup? In-memory caching
- Caching service is the solution. Distributed caching

Figure: Shared DS Market Availability

#### Caching Pattern

- How can multiple instances within multiple apps share something?
- Why not just loading on startup? In-memory caching
- Caching service is the solution. Distributed caching
- You should consider also availability and data consistency

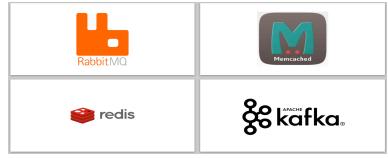

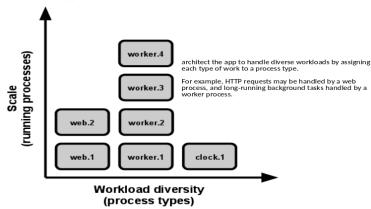

Figure: Shared DS Market Availability

Concurrency

Build your app processes like unix process model based

- 1 \$ wget http://memcached.googlecode.com/files/memcached-1.4.5.tar.gz
- 2 \$ make
- 3 \$ ./memcached -vv
  - Download the application, Install and Start

Logs

#### Logs

Logs are the app assets, and should be handled in a special way

• Logs are streams, and it is not the app job how to save them?

#### Logs

- Logs are streams, and it is not the app job how to save them?
- A dedicated process should do this, and app work is output logs only

#### Logs

- Logs are streams, and it is not the app job how to save them?
- A dedicated process should do this, and app work is output logs only
- You should give attention to what you are logging, that is you may need this data later, even on long term for analysis and reporting

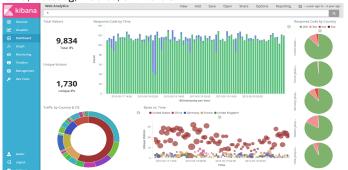

### Logs

- Logs are streams, and it is not the app job how to save them?
- A dedicated process should do this, and app work is output logs only
- You should give attention to what you are logging, that is you may need this data later, even on long term for analysis and reporting
- Today we have some good dedicated software which can aggregate files from different locations, like Logstash and Splunk

### Logs

- Logs are streams, and it is not the app job how to save them?
- A dedicated process should do this, and app work is output logs only
- You should give attention to what you are logging, that is you may need this data later, even on long term for analysis and reporting
- Today we have some good dedicated software which can aggregate files from different locations, like Logstash and Splunk
- Viewing the logs with reports also are different task with different good software like Kibana, Datadog, Fluentd, and others

Disposability

Maximize robustness with fast startup and graceful shutdown

- Disposability
  - Maximize robustness with fast startup and graceful shutdown
  - App's processes are disposable, meaning they can be started or stopped at a moment's notice.

#### Disposability

- App's processes are disposable, meaning they can be started or stopped at a moment's notice.
- Processes should strive to minimize startup time. Ideally, a process takes a few seconds from the time to launch until the process is up and ready to receive requests or jobs

#### Disposability

- App's processes are disposable, meaning they can be started or stopped at a moment's notice.
- Processes should strive to minimize startup time. Ideally, a process takes a few seconds from the time to launch until the process is up and ready to receive requests or jobs
- Processes shut down gracefully when they receive a Shutdown signal

#### Disposability

- App's processes are disposable, meaning they can be started or stopped at a moment's notice.
- Processes should strive to minimize startup time. Ideally, a process takes a few seconds from the time to launch until the process is up and ready to receive requests or jobs
- Processes shut down gracefully when they receive a Shutdown signal
- Worker process, graceful shutdown is achieved by returning the current job to the work queue. For example

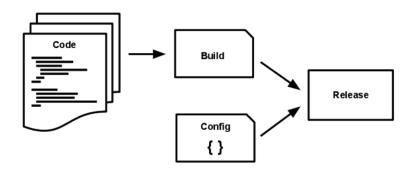

#### Disposability

- App's processes are disposable, meaning they can be started or stopped at a moment's notice.
- Processes should strive to minimize startup time. Ideally, a process takes a few seconds from the time to launch until the process is up and ready to receive requests or jobs
- Processes shut down gracefully when they receive a Shutdown signal
- Worker process, graceful shutdown is achieved by returning the current job to the work queue. For example
  - On RabbitMQ the worker can send a NACK; on Beanstalkd, the job is returned to the queue automatically whenever a worker disconnects. Implicit in this model is that all jobs are reentrant, which typically is achieved by wrapping the results in a transaction, or making the operation idempotent.

#### Disposability

- App's processes are disposable, meaning they can be started or stopped at a moment's notice.
- Processes should strive to minimize startup time. Ideally, a process takes a few seconds from the time to launch until the process is up and ready to receive requests or jobs
- Processes shut down gracefully when they receive a Shutdown signal
- Worker process, graceful shutdown is achieved by returning the current job to the work queue. For example
  - On RabbitMQ the worker can send a NACK; on Beanstalkd, the job is returned to the queue automatically whenever a worker disconnects. Implicit in this model is that all jobs are reentrant, which typically is achieved by wrapping the results in a transaction, or making the operation idempotent.
- Processes should also be robust against sudden death, in the case of a failure in the
  underlying hardware. A recommended approach is use of a robust queueing
  backend, such as Beanstalkd, that returns jobs to the queue when clients disconnect
  or time out.

Dev/prod parity Keep development, staging, and production as similar as possible

Dev/prod parity

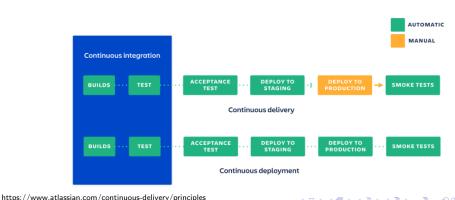

Keep development, staging, and production as similar as possible

• The twelve-factor app is designed for continuous deployment

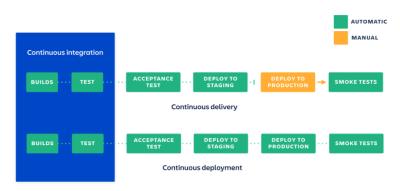

#### Dev/prod parity

- The twelve-factor app is designed for continuous deployment
- The time gap: A developer may work on code that takes days, weeks, or even months to go into production

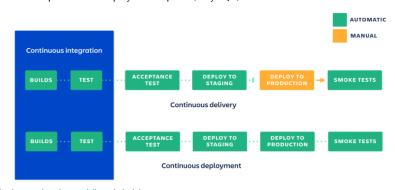

#### Dev/prod parity

- The twelve-factor app is designed for continuous deployment
- The time gap: A developer may work on code that takes days, weeks, or even months to go into production
- The personnel gap: Developers write code, ops engineers deploy it.

#### Dev/prod parity

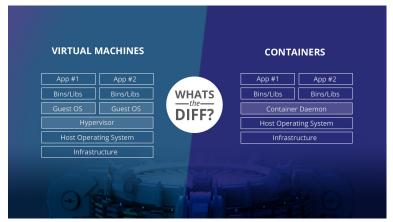

- The twelve-factor app is designed for continuous deployment
- The time gap: A developer may work on code that takes days, weeks, or even months to go into production
- The personnel gap: Developers write code, ops engineers deploy it.
- The tools gap: Developers may be using a stack like Nginx, SQLite, and OS X, while the production deploy uses Apache, MySQL, and Linux.

- Dev/prod parity
  - Keep development, staging, and production as similar as possible
  - The twelve-factor app is designed for **continuous deployment** by keeping the gap between development and production small

#### Dev/prod parity

- The twelve-factor app is designed for continuous deployment by keeping the gap between development and production small
- Dockerization

An orchestrator handles tasks of deploying and managing a set of services. With orchestrator you can

Placing services on nodes.

- Placing services on nodes.
- Monitoring the health of services and restarting unhealthy services.

- Placing services on nodes.
- Monitoring the health of services and restarting unhealthy services.
- Load balancing network traffic across service instances.

- Placing services on nodes.
- Monitoring the health of services and restarting unhealthy services.
- Load balancing network traffic across service instances.
- Service discovery
- Scaling the number of instances of a service

#### Popular Orchestrators

- Docker Swarm
- Kubernates
- AWS ECS
- Service Fabric
- Openshift

## Cloud Services' Deployment

The old and known style is called On-Premise deployment, and it has its cons.

Today we have awesome cloud tools for deployment.

- AWS
- Microsoft Azure

## Monitoring

One of the most hassle part in Microservices is **tracing**! What, How and Why this error occurred?

- Logging
- Tracing
  - Request may span multiple microservices, you should have some tracker over this.
  - Trace ID is a good way to do that
- Monitor matrices
